

Explaining Chemistry with repulsive Frontier Orbitals

Célia Fonseca Guerra

Department of Chemistry and Pharmaceutical Sciences, Vrije Universiteit Amsterdam, The Netherlands
Leiden Institute of Chemistry, Leiden University, The Netherlands

The importance of the Pauli (steric) repulsion in the different types of chemical interactions in supramolecular chemistry will be revealed. With the utilization of Kohn-Sham molecular orbital theory and the energy decomposition analysis, three computational studies will be presented to highlight the manifestation of the Pauli repulsive interactions: i) hydrogen bonding in the mismatched DNA base pairs CC and GG (C=cytosine, G=guanine)¹ and NMR ¹H-shielding constants,² ii) metallophilic interaction in atomic dimers ($M^+ \cdots M^+$) and molecular perpendicular $[H_3P-M-X]_2$ (where M = Cu, Ag, Au and X = F, Cl, Br, I),³ iii) cation selectivity at the internal cavity site of guanine quadruplexes in telomeric DNA.^{4,5} Understanding of the bonding mechanism of these sort of interactions will enable chemists to tune, predict and manufacture new materials in a more efficient way.
